

Questions from Thursday?

Displacement Reactions

Recall: A Single Displacement is when one element replaces another similar element in a compound.

- In order to predict whether a single displacement reaction will take place, we need to refer to an *Activity Series*.
- The activity series is based on the electronegativity of the element - how strongly it will react.
- The activity series of metals is found on p.164 of the text.
- The more reactive the metal, the higher it appears on series. Therefore, Li is at the top, going down to Au and other relatively unreactive metals.
- The activity series of halogens is found on p.168 of the text.
- Similarly, the more reactive the halogen, the higher it appears on series. Therefore, F is at the top of the series.

Examples:

Recall: A Double Displacement is when two reactants recombine to form two new compounds.

There are three main types of double displacement reaction:

- I. Precipitation reactions
- II. Gas-producing reactions
- III. Neutralization reactions

Precipitation Reactions

- In order to predict whether a precipitation reaction will take place, we need to refer to a *Solubility Table*.
- The solubility table is found on p.174 of the text.

Examples:

Gas-producing Reactions

- A double displacement reaction will take place if the reaction produces a gas

Neutralization Reactions

- When an acid and a base are mixed, water will be produced as well as a salt.
